ABSTRACT: Large values of the accelerator impedance influence the motion of trailing particles, in the longitudinal and transverse directions, leading to energy loss, beam instabilities, or secondary effects such as excessive heating of sensitive components at or near the chamber wall (the so-called beam-induced RF heating). Beam-induced RF heating has been observed in many places, for instance in several CERN LHC components during the 2011 and 2012 runs when the bunch/beam intensity was increased and/or the bunch length reduced. This caused beam dumps and delays in operation (reducing integrated luminosity) as well as considerable damage to some equipment. Furthermore, despite the excellent performance of the LHC in 2012, with a record peak luminosity at 4 TeV corresponding to 77 % of the 7 TeV design luminosity of $10^{34}$ cm$^{-2}$s$^{-1}$, the intensity ramp-up was perturbed by several types of instabilities, one of which could not be damped at the end of the run. These limitations could be more severe in the future and therefore impedances should be treated with great care.
Many thanks to all the impedance colleagues, inside CERN and outside CERN => INFN, DESY, TUD, Naples, etc.

INTRODUCTION (7/7)

- **Wake field** = Electromagnetic field generated by the beam interacting with its surroundings (vacuum pipe, etc.)
  - Energy loss
  - Beam instabilities
  - Excessive heating => “Beam-induced RF heating”

- **Impedance** = Fourier transform of the wake field (wake function)

\[ W_t(z) = -\frac{1}{qQ} \int_0^L F_s \, ds = -\frac{1}{Q} \int_0^L E_s \, ds \]

**Diagram:**
- Source => Charge Q
- Test => Charge q
- Bunches 1, 2, 3, 4
- Cavity
- Several types of instabilities perturbed the intensity ramp-up and 1 instability remained at the end of the Run 1 ⇒ Worry for the future…
Reminder: Knobs available to damp transverse coherent instabilities

- Transverse tunes and tune split between the 2 beams
- Coupling between the transverse planes
- Chromaticities (value and sign)
- (Landau) octupoles (value and sign) to increase Landau damping
- Transverse damper (gain and bandwidth: not fully flat / bunch-by-bunch or flat / bunch-by-bunch)
- Bunch length and / or longitudinal profile
1st ramp tried with single-bunch of ~ 1E11 p/b (both B1 and B2) on SA 15/05/2010 without Landau octupoles

=> Bunch unstable at ~ 1.8 TeV for B1 and ~ 2.1 TeV for B2

=> Famous “Christmas tree”

Dedicated study on MO 17/05/2010 at 3.5 TeV

All the lines are spaced by Qs ~ 2E-3
**MEASUREMENTS**

(17/05/2010 at 3.5 TeV)

- Rise-time $\approx 10$ s
- $-20 \, \text{A} < I_{\text{oct}}$ for stability $< -10 \, \text{A}$

**SIMULATIONS**

Scan in octupole current

- Rise-time $\approx 7$ s (0 A)
- Rise-time $\approx 11$ s (-6 A)

- Stability for $I_{\text{oct}} \approx -10$ A

**Head-tail**

$|m| = 1$

Elias Métral, TU Darmstadt, Germany, 02/12/2013

Courtesy of A. Hofmann
Estimation of the rise-time in frequency domain

\[ \text{~24 dB in 24 s} \Rightarrow \text{~9 dB in ~9 s} \]

\[ \Rightarrow \text{Instability rise time ~9 s (consistent with time domain)} \]
TCBI rise-time studies (for mode 0) with 48 bunches (12 + 36)

- Good agreement at 450 GeV

- ~ 2-3 faster rise-times observed at 3.5 TeV (but uncertainty on chromaticities...)

Courtesy of A. Hofmann
**Landau octupoles used at 3.5 TeV to stabilize the beam**

**LOD = - LOF**

- Simulations more critical (but uncertainty on chromaticities, transverse profile - measured by collimation team - different from Gaussian, etc.) => Reasons exist for that and some explanation can be found!
Transverse coherent tune shifts: simulations vs. measurements

=> Everything was for the best in the best of all possible worlds…
Things started to get worse during the 2012 run, which was devoted to LHC exploitation but also to explore the LHC performance limits. => Busy period for us!

Lot of effort devoted to study the main mechanisms alone and interplays between them:
- Impedance, octupoles and transverse damper (and BBLR)
- Impedance and beam-beam (BBLR & BBHO)
- Etc.

Experience from 2012 => “Full” understanding not possible:
- Frequent and simultaneous changes of beam parameters
- Non-conclusive measurements
- Different interpretation of measurements and observations
=> More systematic measurements needed
Lot of effort to refine the LHC impedance model

Nicolas Mounet
First estimate of the HL-LHC impedance model
Observed in several equipment during the 2011-2012 runs when bunch/beam intensity increased and/or bunch length reduced

“beam-screen” of LHC Injection Kicker: ceramic tube with conductors in slots

Beam screen
BEAM-INDUCED RF HEATING (3/9)

- General formula in the case of \( M \) equi-spaced equi-populated bunches (Furman-Lee-Zotter 1986)

\[
P_{\text{loss}} = M I_b^2 Z_{\text{loss}}
\]

\[
Z_{\text{loss}} = 2 M \sum_{p=0}^{\infty} \text{Re}\left[ Z_1(p M \omega_0) \right] \times \text{PowerSpectrum}\left[ p M \omega_0 \right]
\]

- Broad-band impedance (i.e. short-range wake field) \( \Rightarrow \) Sum can be replaced by an integral (\( M \) in front disappears) \( \Rightarrow \)

\[
P_{\text{loss}} \propto M
\]

- Narrow-band impedance (i.e. long-range wake field) \( \Rightarrow \) Only 1 term in the sum \( \Rightarrow \)

\[
P_{\text{loss}} \propto M^2
\]

Elias Métral, TU Darmstadt, Germany, 02/12/2013
Family of (finite) distributions, depending on $n$ (keeping the same HWHH) and converging to a Gaussian when $n$ goes to infinity.

For LHC in 2011 (=> 9 cm rms)

$\tau_b = 4 \sigma_t = 1.2 \text{ ns}$
**BEAM-INDUCED RF HEATING (5/9)**

- **Power loss formula for the case of a (sharp) resonance (i.e. with only 1 line)**
  \[ P_{\text{loss}}^{\text{On-resonance}} = R I^2 \times F \]

  \[ Q \gg \frac{f_r}{2 f_b} \]

  \[ F = 10 \log_{10} \left( \frac{P_{\text{dB}}(f_r)}{10} \right) \]

  \[ R = 2 R_i, \text{ i.e. using the Linac convention (LinacOhm)} \]

  \[ I = \text{Total beam current [in A]} = M \times I_b \]

  \[ F = e^{-\left(2\pi f_r \sigma_t \right)^2} \]

- **In the case of a Gaussian bunch**

- **Bunch frequency**

**Elias Métral, TU Darmstadt, Germany, 02/12/2013**
Huge effect of the bunch length and / or longitudinal profile

=> Ex. with a 1 A beam and a shunt impedance $R_l = 5 \, \text{k\,\Omega}$ at 1.4 GHz

$P_{\text{dB}}(f) = 10^{-4}$

$\tau_b = 1.2 \, \text{ns}$

5 k\,\Omega gave 1 W at 1.4 GHz for 9 cm =>
Becomes ~ 2 kW for 4.5 cm
BEAM-INDUCED RF HEATING (7/9)

- Off-resonance effect

=> Valid when $Q >> 1$ and $\Delta << 1$

\[ P_{\text{loss, off-resonance}} = P_{\text{loss, on-resonance}} G \]

\[ G = \frac{\Delta^2}{\Delta^2 + \sin^2\left(\frac{\pi f_r}{f_b}\right)} \]

\[ \Delta = \frac{\pi f_r}{2 Q f_b} \]
BEAM-INDUCED RF HEATING (8/9)

- Usual solutions to avoid RF heating => Depending on the situation
  - Increase the distance between the beam and the equipment
  - Coat with a good conductor (if resistive losses and not geom.)
  - Close large volumes (could lead to resonances at low frequency) and add a smooth transition => Beam screens, RF fingers etc.
  - Put some ferrite with high Curie temperature and good vacuum properties (close to maximum of magnetic field of the mode and not seen directly by the beam) or other damping materials (AlN-SiC Ceralloy 13740Y as in PEP II => S. Novokhatiski):
    - Power loss can be significantly decreased
    - The ferrite should absorb the remaining (much smaller) power => Still potential issue of heating due to bad contact / conduction
  - Increase the bunch length (if possible). The longitudinal distribution can also play a very important role for some devices, and it should be kept under tight control
Improved subsequent heat transfer:
- Convection: none in vacuum
- Radiation: usually, temperature already quite high for radiation to be efficient. One should therefore try and improve the emissivities of surrounding materials
- Conduction: good contact and thermal conductivity needed
- Active cooling: LHC strategy was to water cool all the near beam equipment

Try and design an All Modes Damper (AMD) if possible, to remove the heat as much as possible to an external load outside vacuum, where it can be more easily cooled away. This can also work together with a damping ferrite

Install temperature monitoring on critical devices to avoid possible damages
Why do we need RF fingers (and or ferrite)? => To avoid having too large impedances (longitudinal or transverse) due to (big) changes of geometry for moving equipments, which can lead to

- Beam-induced RF heating (if real part of longitudinal impedance)
- Longitudinal or transverse beam instabilities (if real and/or imaginary parts of longitudinal or transverse impedances)

Example of RF fingers:
PIMs = Plug-In Modules

Example of ferrite tiles:
Installed in the new VMTSA in 2012

Initial dimensions (quickly available!):
~ 12 cm × 3 cm × 1 cm
1) Funnel for the PIMs
   - For case of longitudinal movement (only)
   - Good for contact / gap
   - Possible issue with buckling and aperture restriction

2) Spring for the VMTSA
   - For case of transversal movement
   - Possible issue with contact / gap (due to elliptical shape)
   - Possible issue with aperture restriction
   - Possible issue with RF heating
   - Spring (to be put at the extremity of the RF fingers where there is a groove)
   - Conforming RF fingers
   - Big gap created in case the spring is NOT in place

RF contact fingers to shield the distorted geometry of the bellows from the beam
3) Fixed extremities for the LHCb VELO (VErtex LOcator)
   - Seems to work very well!
   - Well-studied VELO design in terms of impedance effects paid off => No issue observed

4) New RF design from TE/VSC
   - 1st prototype based on 2 convolutions manufactured in 2012
   - Issue: Imaginary part of the longitudinal impedance (if many and if not elongated)
5) Longitudinal sliding contacts for collimators

- Initial proposal for 1st (SPS) prototype (2003)
- Uncoated CuBe fingers sliding on C/C
- Electrical contact resistance ~ 30 mΩ (specification: 1 mΩ)

=> Redesign necessary
RF fingers for PIMs
- Low contact resistance < 0.1 mΩ (i.e. 3 mΩ / RF finger as there are 30 RF fingers in \(//\))
- No cold welding
- Low friction
- Good formability properties

RF fingers for collimators
- Same as above with contact resistance < 1 mΩ
- Resistance to bake out: 250°C / 1000 h
- Resistance to heating => Good thermal conductivity
- Wear after many cycles “open-close of the jaws” (1500 cycles ~ 4 years)

Good electric contacts requires
- Low surface roughness
- Soft metals (at least one)
- No oxide layer at the surface
CERN RF FINGERS TASK FORCE IN 2012 (6/9)

- 1800 X-rays taken in 2012
- 92 Nonconformities (~ 5 %) => 2 types of design: circular and elliptical (VMTSA)
CERN RF FINGERS TASK FORCE IN 2012 (7/9)

NONCONFORMITIES
Guidelines for RF fingers

- **CuBe** => Grade important in case of bake-out as for collimators (=> C17410)
- **CuBe** is a good conductor but still has too an high surface impedance => Coating needed to increase surface conductivity, reduce contact resistance and avoid cold welding => 2 possible solutions to avoid cold welding
  - Putting a diffusion barrier between the 2 metals (i.e. an oxide layer) => Bad for electrical contact
  - Choosing metals with low solubility => Adopted solution: Au-Rh for the PIMs (Ag-Rh is quite similar). The contact surface on the insert should be electro-polished before putting the Rh coating
- Collimators needs a bake-out at 250°C => Au cannot be used at this temperature because of the diffusion of Cu into Au => Ag used
- For the MKI injection kickers, SS (instead of CuBe), but still Au plated, is used for the RF fingers because of the bake-out at ~ 300°C (CuBe would lead to a very small residual elasticity of ~ 20% only)
- Top priority: Try and achieve robust mechanical designs to keep the contacts of all the RF fingers and do a very careful installation
Guidelines for ferrite

- If RF fingers cannot be used or in case of nonconformities, some trapped modes might be created and ferrite tiles can be used to damp these modes.

- The ferrite should be put at (or close to) the maximum of the magnetic field of the mode to be damped (at the metallic wall), which is deduced after detailed electro-magnetic simulations, assuming known electro-magnetic properties of the ferrite. The ferrite should not be seen directly by the beam (if possible) and depending on the frequency of the mode to be damped, the ferrite type and thickness need to be optimized.

- Furthermore, the ferrite should be compatible with UHV (Ultra High Vacuum) and even if the ferrite will considerably reduce the power loss (by lowering the quality factor Q of the resonance, while keeping R/Q constant), the remaining power loss will be absorbed by the ferrite which will heat and might reach its Curie temperature (and therefore lose its damping properties) if the heat transfer is not optimized.
A mini-workshop on "Simulation of Power Dissipation and Heating from Wake Losses in Accelerator Structures" took place on 30/01/2013 at the DLS => http://www.diamond.ac.uk/Home/Events/Past_events/Simulation-of-Power-Dissipation---Heating-from-Wake-Losses.html

Organised by G. Rehm

Why are we worried?

- Diagnostics systems are designed to couple to the beam.
- Wake loss factor is large enough to give uncomfortably large amounts of energy being lost from the beam.
- We plan to go to higher currents and shorter bunches.
- Current settings imply 189W lost in striplines
- Planned settings imply 313W lost in striplines

Heat cap. 0.23 [kJ/kgK]
Diffusivity 8.000e+16 [m^2/s]
Young's Mod. 76 [GPa]
Pois.Ratio 0.37
Thermal Exp. 20 [1e-6/K]

Background (vessel) is stainless steel
1.5e6 S/m
Silver wires (yellow) have a constant radius of 1.53mm
Satisfactory results obtained with striplines and BPMs (comparing temperatures) but still not an easy work and discussions ongoing.
**CONCLUSION (1/2)**

- **Great success for the LHC performance**
  - \( \sim 1.6 \times 10^{11} \text{ p/b} \) instead of nominal \( 1.15 \times 10^{11} \text{ p/b} \) \( \Rightarrow + \sim 40\% \)
  - \( \sim 2.2 \mu\text{m} \) instead of nominal \( 3.75 \mu\text{m} \) \( \Rightarrow - \sim 40\% \)

\[ \Rightarrow \text{Bunch brightness: } \sim (1.6 / 1.15) \times (3.75 / 2.2) \sim 2.4 \text{ times larger than nominal!} \]

- **Both transverse damper and Landau octupoles are needed and work well! High chromaticity used at high energy**

- **However,**
  - **The End-Of-The-Squeeze Instability could not be cured (not understood yet)** \( \Rightarrow \text{Potential worry for future operation at higher energy, higher beam intensity and higher beam brightness} \)

- **Many beam-induced RF heating issues**
CONCLUSION (2/2)

● Lot of work at CERN on impedances over the last few years
  ▪ LHC and HL-LHC
    • Impedance and related (transverse) instabilities
    • Beam-induced RF heating
  ▪ LHC injectors within the LIU (LHC Injectors Upgrade) project
    ▪ SPS, PS and PSB => Reliable impedance models under development

● Next important event for impedance studies

=> Workshop on "Electromagnetic Wake Fields and Impedances in Particle Accelerators", Erice (Sicily, Italy), 23-29/04/2014 (Organisers: V. Vaccaro and E. Métral)

=> Everybody welcome!
