

Nested Head-Tail Computations for LHC

The computations are done by A. Burov (LARP-LTV) at November 2012 with his program NHT [1] (Acknowledgements to SlavaD, EliasM, NicolasM, SimonW, XavierB, TatianaP).

Generally, NHT is a Vlasov solver for transverse beam instabilities. It assumes arbitrary multi-bunch beam with arbitrary train structure, arbitrary impedance, arbitrary frequency profile of the damper gain, arbitrary transverse and longitudinal nonlinearities and beam-beam collision scheme. The corresponding functions are supposed to be provided in any form.

The program computes all the relevant coherent modes with their head-tail, radial and couple-bunch structure for a given gain amplitude and beam chromaticity.

After that, the threshold strength of the Landau elements (MO currents for LHC) is computed by means of pre-calculated stability diagrams.

The NHT is under construction, being extended, upgraded and anti-bug checked day after day.

Nominal Impedance, Single Bunch, M0+

SB stabilizing octupole current, A

Octupoles vs Q' and gain

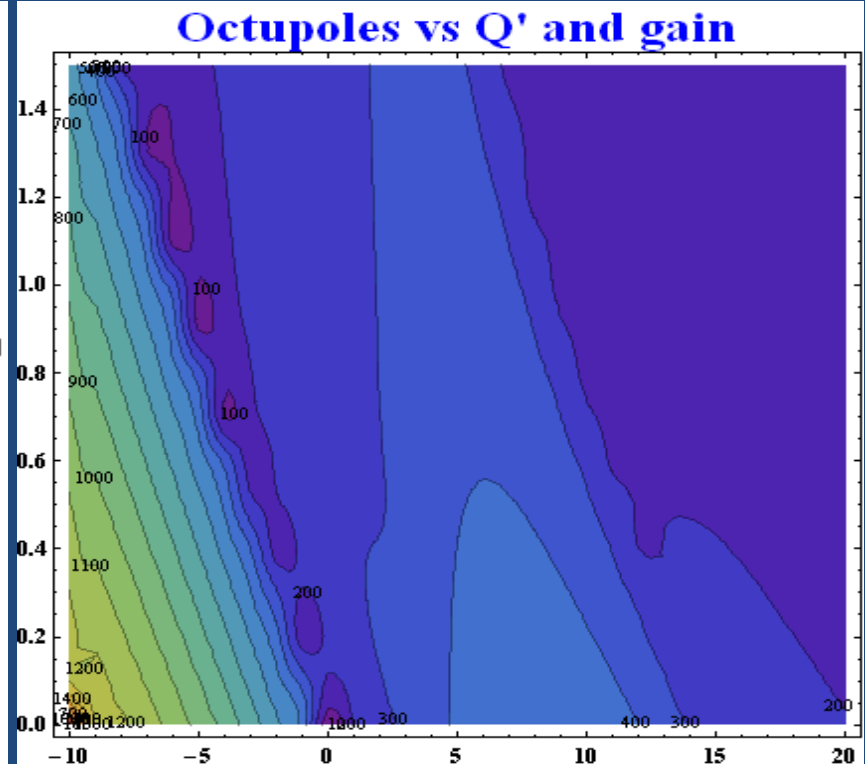

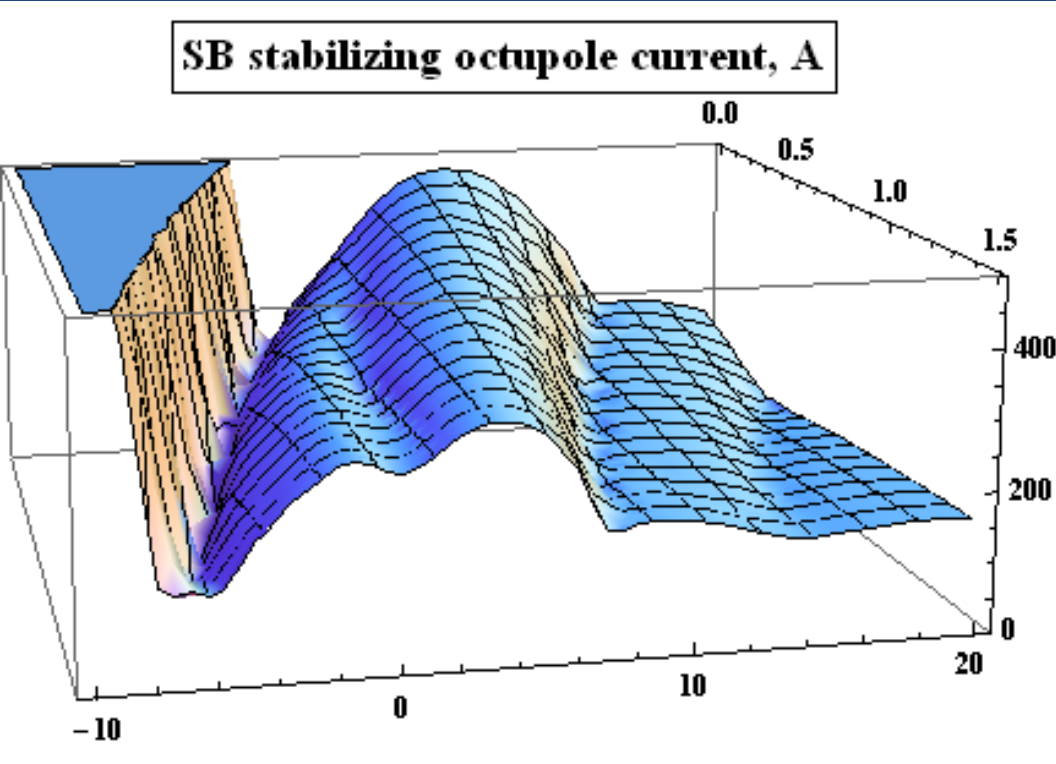

Q' : 5,10,20

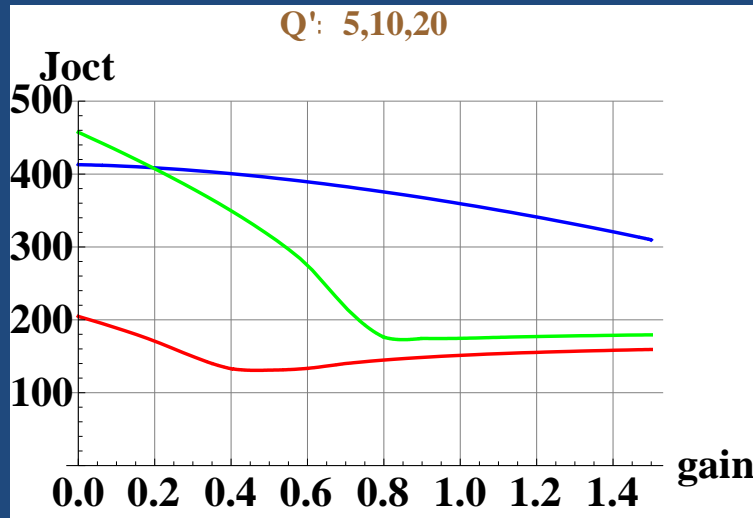

gain: 0, 0.7, 1.4

2⊗ Impedance, Single Bunch, M0+

The Valley is lost...

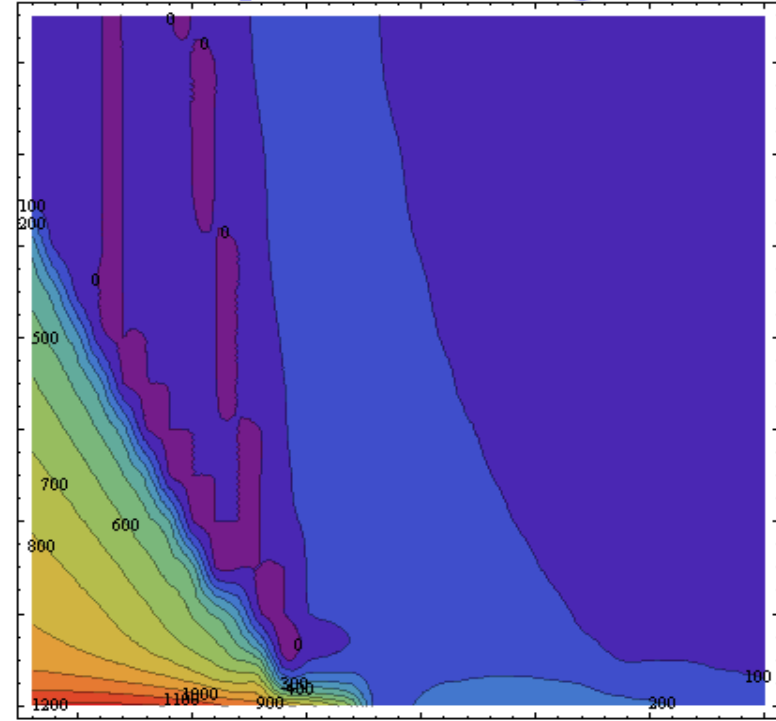

1⊗ Impedance, CB, MO+, old ADT

CB stabilizing octupole current, A

Octupoles vs Q' and gain

At high enough gain, CB and SB thresholds are the same.

Bunch centers do not move, so bunches do not cross-talk. CB instabilities are essentially SB.

Q' : 5,10,20

gain 0, 0.7, 1.4

2⊗ Impedance, CB, MO+, old ADT

CB stabilizing octupole current, A

Octupoles vs Q' and gain

Q': 5,10,20

gain: 0, 0.7, 1.4

2⊗ Impedance, CB, MO+, new bbb ADT

CB stabilizing octupole current, A

Octupoles vs Q' and gain

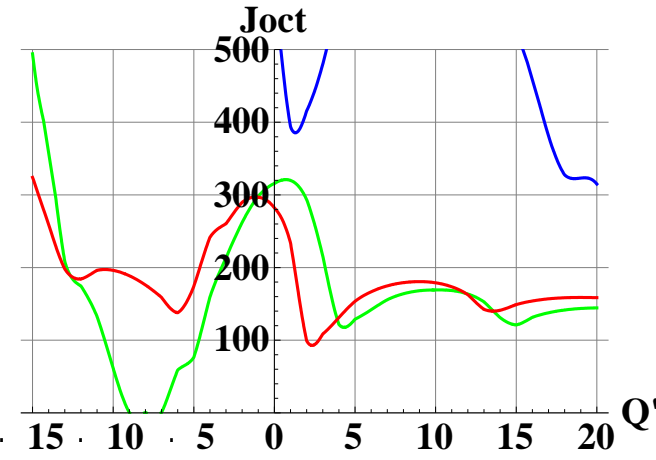

The Valley is back

Q' : 5,10,20

gain: 0, 0.7, 1.4

2⊗ Impedance, CB, MO+, new bbb ADT, 90°+30°

CB stabilizing octupole current, A

Octupoles vs Q' and gain

No big difference with 90°.

Q': 5,10,20

gain 0, 0.7, 1.4

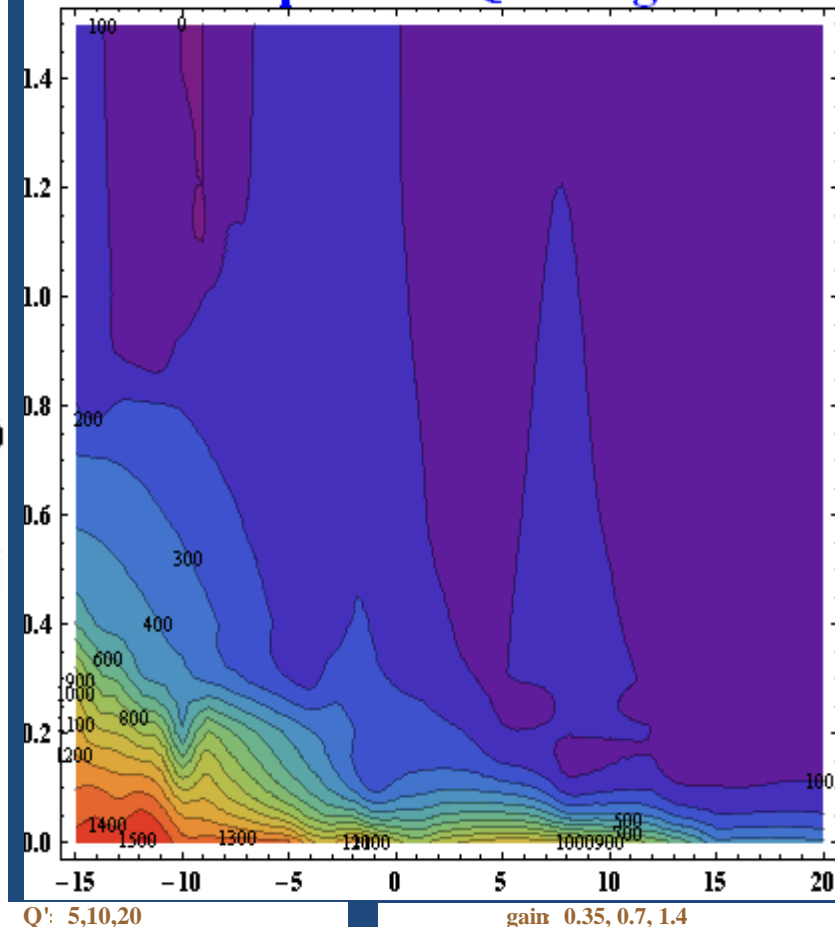

1⊗Imp, CB, CBB $d\phi_{15}=\pi/2$, MO+, bbb ADT

BB-CB stabilizing octupole current, A

incoherent $dQ_{bb}/Q_s|_{IR1,5} = \pm 1.1$; $d\phi_{15} = \pi/2$

Octupoles vs Q' and gain

Q' : 5,10,20

gain: 0.35, 0.7, 1.4

Valley is at its threshold with that beam-beam.

1⊗Imp, CB, CBB $d\phi_{15}=\pi$, MO+, bbb ADT

BB-CB stabilizing octupole current, A

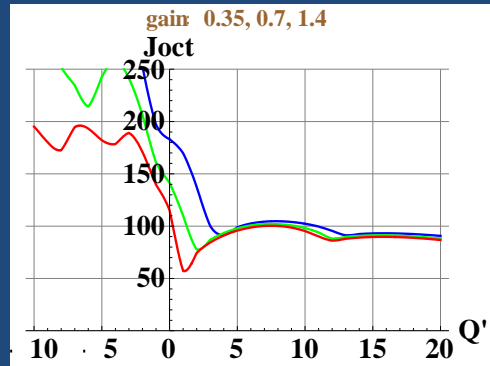

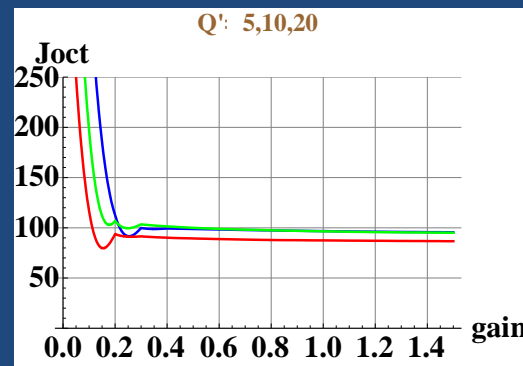

incoherent $dQ_{bb} / Q_s|_{IR,1,5} = \pm 1.1$; $d\phi_{15} = \pi$

Octupoles vs Q' and gain

No valley with that beam-beam.

2⊗ Impedance, CB, CBB, MO+, new bbb ADT, 90°

BB-CB stabilizing octupole current, A

incoherent $dQ_{bb} / Q_s|_{IR1,5} = \pm 1.1$; $d\phi_{15} = \pi$

Octupoles vs Q' and gain

Essentially, it scales linearly with impedance

Q': 5,10,20

gain: 0.35, 0.7, 1.4

Comparison of NHT with tracking of Simon White

Highest growth rates for single bunch, gain=1.4 and nominal impedance
