

TUTORIALS for the course of “Collective Effects in Beam Dynamics” (EM) – 3rd day

COASTING-BEAM TRANSVERSE COHERENT INSTABILITIES

- 1) Derive the equation of motion of page 3.
- 2) What would be the instability rise-time (see page 10) in the following conditions?
 - Horizontal tune: $Q_{x0} = 6.25$.
 - Resonator impedance: $f_r = 1 \text{ GHz}$, $R_x = 3 \text{ M}\Omega/\text{m}$ and $Q = 1$.
 - $\gamma = 6$.
 - Number of protons: $N_b = 10^{14}$.
 - Machine radius: $R = 100$.

Draw the shape of the resonator impedance (from $-\infty$ to $+\infty$).

- 3) In the case of betatron frequency spread through momentum spread only (see page 50), what happens if the slip factor is $\eta = -0.1$ and the chromaticity $\xi = +0.1$? What do you propose to improve the situation?

What happens right at transition?

- 4) What happens in the case of betatron frequency spread through momentum spread only (see page 52) if the real part of the coherent tune shift is $-0.9\text{E-}3$, the imaginary part of the coherent tune shift $-0.7\text{E-}3$ and the tune spread is $\Delta Q_p = \frac{4}{3} 10^{-3}$ (the revolution frequency is 471 kHz)? Is the beam unstable? If yes, what is the instability rise-time and by how much should we increase the tune spread to stabilize the beam? How could we do that?

BUNCHED-BEAM TRANSVERSE COHERENT INSTABILITIES

- 1) Applying Sacherer's formula (page 51) to the impedance of the previous exercise 2), what would be the horizontal coherent tune shift for the first 3 head-tail modes in the same conditions as exercise 2) with in addition an horizontal chromaticity $\xi_x = 0$ and a full (4σ) bunch length $\tau_b = 500 \text{ ns}$.

Hint: It is a simple computation.

- 2) Will the instability of page 56 be faster if the chromatic frequency is doubled? How will the signal at a Beam Position Monitor look like (assuming that the instability is not damped by another mechanism)?
- 3) Looking at the figures of pages 79 and 80, explain why in the first case the coupling between modes 0 and -1 will be weak and will lead to mode coupling-

decoupling, whereas in the second picture the coupling between modes 0 and -1 will lead to a strong instability.
